# THREAT ADVISORY

 **ATTACK REPORT**

## **StaryDobry Campaign: Trojanized Games Fuel a Global Cybercrime Wave**

Date of Publication

February 19, 2025

Admiralty Code

A1

TA Number

TA2025049

# Summary

**Attack Discovered:** December 31, 2024

**Targeted Country:** Worldwide

**Targeted Industries:** Gaming

**Campaign Name:** StaryDobry

**Malware:** XMRig cryptominer

**Attack:** A large-scale malware campaign, dubbed "StaryDobry," has been spreading trojanized versions of cracked games to unsuspecting gamers worldwide. Games such as Garry's Mod, BeamNG.drive, and Dyson Sphere Program have been weaponized to distribute the XMRig cryptominer, impacting both individual users and businesses. This previously unidentified threat actor has been actively targeting users across multiple countries, including Russia, Brazil, Germany, Belarus, and Kazakhstan. By leveraging torrent sites as the primary distribution channel, the attackers have been able to infect a wide range of victims looking for pirated software. Once installed, the cryptominer covertly hijacks system resources to mine cryptocurrency, degrading performance while generating illicit profits for the attackers.

# Attack Details

## #1

Cybercriminals executed a large-scale malware campaign, infecting thousands of systems worldwide. The attack, which lasted a month, relied on trojanized versions of popular games distributed via torrent sites. By employing advanced evasion techniques, the attackers bypassed security defenses, allowing the malware to spread undetected. At its core, the campaign deployed a modified **XMRig** cryptominer, hijacking victims' CPU and GPU resources to mine cryptocurrency, significantly degrading system performance.

## #2

The infection wave peaked on December 31, 2024, when compromised game installers flooded torrent trackers. However, this was a calculated operation—threat actors had preloaded these malicious repacks as early as September 2024. They specifically targeted lightweight simulator and sandbox games, ensuring a broad reach among users.

## #3

The malware activates when a victim launches what appears to be a legitimate 32-bit Windows game installer. Instead of delivering the expected game, it triggers a multi-stage attack designed to evade detection and establish persistence. It first extracts its malicious payload and performs environment checks to detect debugging or virtualized setups, attempting to thwart security researchers. To further obscure its presence, the malware registers unrar.dll as a command handler using regsvr32.exe and queries the victim's IP address to determine their location. If this check fails, it defaults the region to China (CN) or Belarus (BY), likely as a misdirection tactic.

## #4

Once these checks are complete, the malware contacts a hardcoded command-and-control (C2) server, enabling attackers to issue commands and update the payload. To uniquely identify each infected system, it generates a Base64-encoded fingerprint using MachineGUID from the Windows registry, encrypts it using SHA-256, and stores it in a decoy file to mislead security tools.

## #5

At this stage, unrar.dll delivers the final payload, MTX64.exe, encrypted with AES-128. To blend in, the malware spoofs system resources, embedding legitimate DLL properties and modifying timestamps to avoid detection. Once executed, it masquerades as a Windows Shell Extension Thumbnail Handler, using the GetThumbnail function to launch a hidden execution thread.

## #6

For persistence, the malware continuously verifies its presence by checking the hashed MachineGUID. It also listens for JSON-formatted commands from its C2 server. If specific codes (322 or 200) are received, the malware extracts an MD5 checksum, downloads the next-stage payload, verifies its integrity, decrypts it, and stores it for execution. To automate the attack, it creates a scheduled task using Windows Task Scheduler.

## #7

The StaryDobry campaign highlights the growing threat of malware-laced pirated software. By embedding malicious code into game installers, cybercriminals have compromised thousands of systems worldwide. As torrent sites remain a key vector for malware distribution, users must exercise caution, while organizations should strengthen their defenses with network monitoring, endpoint detection, and PowerShell logging to mitigate such threats.

# Recommendations

**Use Licensed Software:** Avoid pirated or unlicensed software, as it poses significant security risks. Cybercriminals frequently embed malware in such tools, making them a common attack vector. To ensure system integrity and security, always obtain software from official and trusted sources.

**Enhance Endpoint Protection:** Deploy next-generation antivirus (NGAV) and endpoint detection & response (EDR) solutions to identify and block malware. Leverage behavioral analysis and machine learning-based detection to spot suspicious activity.

**Monitor and Restrict Network Traffic:** Continuously analyze outbound connections to identify potential communication with malicious command-and-control (C2) servers. Implement DNS filtering and block access to known harmful domains to prevent unauthorized data exfiltration.

## Potential MITRE ATT&CK TTPs
