 **ATTACK REPORT**

When AI Turns Against You: The Malvertising Trap of Kling AI

Date of Publication

May 22, 2025

Admiralty Code

A1

TA Number

TA2025160

Summary

First Seen: 2025

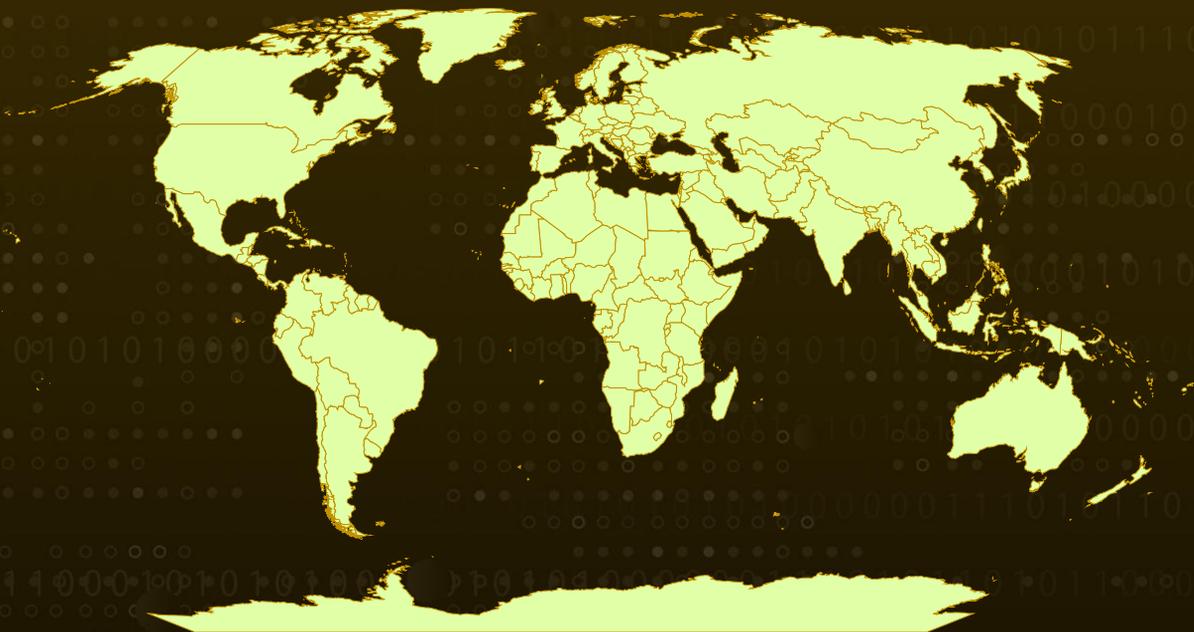

Malware: PureHVNC RAT

Targeted Industries: Banking, cryptocurrency

Targeted Countries: Worldwide

Attack: In early 2025, attackers launched a deceptive campaign by impersonating Kling AI, to trick users into downloading malware. Promoted heavily through fake social media ads, the campaign led victims to a bogus website where they were lured into clicking a button only to receive a malicious ZIP file containing a disguised Windows executable. This file triggered a stealthy loader, designed to evade detection, establish persistence, and inject a second-stage payload. That payload was a customized PureHVNC Remote Access Trojan (RAT), capable of full system control, surveillance, and data theft.

Attack Details

#1 In early 2025, a deceptive cyber campaign was uncovered that impersonated Kling AI a well-known platform for generating AI-based images and videos. The attackers set up a convincing fake website that tricked users into believing they were using a legitimate AI tool. Instead of receiving actual media content, users were duped into downloading malicious files disguised as image or video outputs. These files used double extensions and special characters like Hangul Fillers to conceal their true nature as Windows executable files. Once executed, they triggered a stealthy loader built with .NET Native AOT (Ahead-of-Time) Compilation, helping it evade antivirus detection.

#2 The attack chain began with social media malvertising. Researchers identified over 70 fake promoted posts mimicking Kling AI across various platforms. When users visited the fraudulent AI site and interacted with it such as uploading an image or clicking the “Generate” button they were served a ZIP archive containing a single .exe file. Though named to resemble a media file, it was actually an application, with a 292-byte filename designed to obscure its real identity.

#3 The first-stage loader was developed in .NET and incorporated multiple evasion tactics, including checks for virtual environments and the presence of analysis tools like Wireshark, Procmon, and OllyDbg. To maintain persistence, it created a registry run key and dropped a copy of itself in the %APPDATA%\Local directory. It then injected a second-stage payload into trusted system processes such as InstallUtil.exe or AddInProcess32.exe, allowing it to operate under the radar.

#4 The second-stage payload, often obfuscated using .NET Reactor, delivered a tailored version of the PureHVNC Remote Access Trojan (RAT). This RAT provided attackers with full remote control over the compromised machines and included capabilities such as keylogging, data theft, and remote desktop access. One of its plugins, PluginWindowNotify, actively monitored foreground windows for keywords like “crypto” or “bank,” taking screenshots and alerting the attacker when sensitive information was detected.

#5 Clues in the campaign, including Vietnamese language strings in the code, ad locations, and names associated with financial transactions, suggested Vietnamese threat actors were behind the operation. This campaign is a strong reminder of how threat actors are increasingly combining social engineering, evasive malware techniques, and AI-themed lures to compromise users at scale.

Recommendations

Be cautious of AI tools promoted via social media ads: Avoid downloading software or files from promoted posts or unofficial sources. Always verify URLs and stick to the legitimate websites of AI tools like Kling AI.

Enhance Endpoint Protection: Deploy next-generation antivirus (NGAV) and endpoint detection & response (EDR) solutions to identify and block malware. Leverage behavioral analysis and machine learning-based detection to spot suspicious activity.

Block known malicious domains and fake AI websites: Continuously update web filters and DNS security solutions to block access to domains used in this and similar campaigns. Monitor for newly registered domains that imitate popular AI services.

Disable autorun execution of unknown files: Apply group policies to restrict execution from locations like %APPDATA% or %TEMP% to minimize the impact of droppers that attempt to persist using these paths.

Educate users about deceptive file types: Train employees to recognize suspicious file names, especially those using double extensions (e.g., .jpg.exe) or unusual characters like Hanguul fillers designed to mask executables as media files.
