GoBruteforcer Exposed: How Weak Credentials Power a Silent Linux Botnet

Date of Publication

January 8, 2026

Admiralty Code

A1

TA Number

TA2026007

Summary

Attack Discovered: 2023

Targeted Region: Worldwide

Malware: GoBruteforcer (also called GoBrut)

Targeted Industries: Cryptocurrency

Affected Platform: Linux

Attack: GoBruteforcer is a modular Go-based botnet that compromises Linux servers by brute-forcing weak credentials on internet-exposed services such as FTP, MySQL, PostgreSQL, and phpMyAdmin, spreading through a structured infection chain that includes web shells, downloaders, IRC bots, and dedicated bruteforcer modules. The campaign is driven by the widespread reuse of AI-generated deployment examples that propagate common usernames and insecure defaults, alongside legacy web stacks like XAMPP that expose FTP and administrative interfaces with minimal hardening, leaving an estimated 50,000+ servers at risk. The operators show a clear financial motive, deploying additional Go-based tools to target cryptocurrency infrastructure, including TRON balance scanners and token-sweeping utilities for TRON and Binance Smart Chain, with on-chain analysis confirming successful theft. The 2025 variant represents a technical step forward, introducing a fully rewritten Go-based IRC bot with Garble obfuscation, process-masking for stealth, and more resilient command-and-control infrastructure.

Attack Details

#1

GoBruteforcer is a steadily evolving Linux botnet written in Go that has grown far more capable since it first surfaced in 2023. Rather than relying on a single exploit, the malware follows a deliberate, multi-stage infection chain that capitalizes on weak credentials and exposed services. Initial access is typically achieved by brute-forcing FTP logins, abusing misconfigured MySQL servers, or breaking into publicly accessible phpMyAdmin panels. Systems running XAMPP are particularly attractive targets, as its default setup often exposes FTP services mapped directly to web-accessible directories, creating an easy bridge from credential access to code execution.

#2

Once attackers gain a foothold, they move quickly to establish control by uploading a PHP web shell into the compromised webroot. This web shell serves as a remote command console, allowing operators to execute arbitrary commands and prepare the system for deeper infection. From there, the attackers deploy the next stage: an IRC-based control bot. Using the web shell, architecture-specific binaries are downloaded and executed. Afterward, the bot connects back to the attacker-controlled command-and-control infrastructure over the IRC protocol, typically on TCP port 8080.

#3

The IRC bot acts as the central coordinator for further activity on the host. Through it, the attackers push down a dedicated bruteforcer module that is periodically updated and relaunched. This component continuously scans random public IP ranges, attempting credential-based logins against exposed services. The design is efficient and persistent, ensuring that compromised servers are not just victims, but active participants in expanding the botnet and harvesting new access points across the internet.

#4

The 2025 variant marks a clear technical leap. The IRC bot has been completely rewritten in Go and protected with Garble obfuscation to hinder analysis. To stay hidden, the malware masks its process name using the prctl system call, often presenting itself as the legitimate “init” process, and overwrites its command-line arguments to evade common monitoring tools. It also introduces multiple fallback command-and-control mechanisms, allowing it to recover even if primary servers are disrupted, and is compiled in multiple architecture-specific builds to maximize reach across x86, x64, and ARM-based systems.

#5

At the heart of GoBruteforcer’s success is its disciplined approach to credential abuse. Each brute-force task receives around 200 credentials from the C2 server, drawn from a larger pool of 375 to 600 commonly reused weak passwords. The malware favors predictable operational usernames such as “appuser,” “myuser,” “root,” “wordpress,” and crypto-themed variants.

#6

Millions of FTP, MySQL, and PostgreSQL servers remain publicly reachable, and researchers estimate that more than 50,000 systems are immediately vulnerable to GoBruteforcer-style attacks. Beyond simple access harvesting, the operators have demonstrated clear financial motives, especially in cryptocurrency-related campaigns. On compromised hosts, uncovered Go-based tools designed to scan TRON wallets, sweep tokens from TRON and Binance Smart Chain accounts, and automate fund transfers. In one case, data files containing around 23,000 TRON addresses were recovered, and on-chain analysis confirmed successful transfers to attacker-controlled wallets, underscoring that these attacks are not just theoretical, but actively monetized.

Recommendations

Audit Internet-Exposed Services: Immediately identify and inventory all FTP, MySQL, PostgreSQL, and phpMyAdmin services exposed to the internet on your network perimeter.

Review Cron Jobs: Examine all cron entries on Linux servers for suspicious persistence mechanisms executing binaries from /tmp, /var/tmp, /dev/shm, or /run/lock directories.

Enforce Strong Authentication: Implement password complexity requirements (minimum 16 characters, mixed case, numbers, symbols). Deploy multi-factor authentication for all administrative interfaces. Rotate all credentials for FTP, MySQL, PostgreSQL, and phpMyAdmin services

Restrict Network Exposure: Disable or firewall internet-facing FTP, MySQL, and PostgreSQL services unless absolutely required. Implement IP whitelisting for administrative interfaces. Deploy phpMyAdmin behind VPN or internal-only access

Monitor IRC Traffic: Alert on outbound connections to port 8080 and unusual IRC protocol activity from internal servers.
